## In the CLAIMS

1. (currently amended) A method of performance monitoring in a communications network, comprising;

monitoring a signal over time by allocating a current signal quality characterization to the signal, selected from at least three two such signal quality characterizations;

identifying a plurality of time intervals making up a continuous succession of such time intervals, such that a current time interval is terminated and a next time interval is initiated each time the signal quality characterization allocated to the signal changes; and

generating a record of each identified time interval.

wherein the at least three two signal quality characterizations are selected from the following:

Perfect Time Interval (PT), which is allocated to the signal where no errors are detected on the signal;

Errored Time Interval, which is allocated to the signal where errors are detected on the signal in a unit time in insufficient numbers to make a service carried by the signal unavailable;

Severely Errored Time Interval, which is allocated to the signal where errors are detected on the signal in a unit time in sufficient numbers to make a service carried by the signal unavailable;

Unavailable Time Interval (UAT), which is allocated to the signal where a service carried by the signal is unavailable; and

Poor Time Interval (PrT), which is allocated to the signal where a sequence of at least two of the above characterizations are detected on the signal.

- 2. (original) A method according to claim 1 additionally comprising generating a performance log using the records.
- 3. (cancelled)

- 4. (original) A method according to claim 1 wherein monitoring occurs over successive log periods and the method comprises generating a performance log using the records for each log period.
- 5. (original) A method according to claim 1 wherein the record for each interval comprises at least the length of the interval and the signal quality characterization allocated for the interval.
- 6. (original) A method according to claim 1 comprising generating a performance log made up of records stored in accordance with the succession of time intervals.
- 7. (original) A method according to claim 1 comprising generating a performance log by manipulating selected records to reduce the amount of memory required to store the records while intelligently degrading their accuracy.
- 8. (original) A method according to claim 1 additionally comprising selecting sets of records corresponding to continuous successions of time intervals, and merging the selected sets to form a merged record.
- 9. (original) A method according to claim 1 additionally comprising:

designating some records as primary records and others as secondary records;

selecting sets of secondary records corresponding to continuous successions of time intervals; and

merging the selected sets to form a merged record.

10. (original) A method according to claim 1 additionally comprising:

designating records as primary records if they fall within one or more sets of the longest records having a selected quality characterization and designating other records as secondary records; selecting sets of secondary records corresponding to continuous successions of time intervals; and

merging the selected sets to form a merged record.

11. (original) A method according to claim 1 additionally comprising:

designating some records as primary records and others as secondary records;

selecting sequences of secondary records corresponding to continuous successions of time intervals which are located between two primary records; and merging the selected sets to form a merged record.

12. (original) A method according to claim 1 additionally comprising:

designating some records as primary records and others as secondary records;

selecting sets of secondary records corresponding to continuous successions of time intervals; and

merging the selected sets to form a merged record;

wherein secondary records are designated as such according to one or more of the following:

records representing the shortest intervals of time; and

records corresponding to the highest densities of continuous successions of time intervals.

13. (original) A method according to claim 1 additionally comprising monitoring the amount of memory required to store the records, and when the amount of memory reaches a predetermined limit, selecting sets of records corresponding to continuous successions of time intervals, and merging the selected sets to form a merged record so as to reduce the amount of memory required to store the records.

14. (original) A method according to claim 1 additionally comprising:

designating some records as primary records and others as secondary records;

selecting sets of secondary records corresponding to continuous successions of time intervals:

merging the selected sets to form a merged record; and

storing primary records, unmerged secondary records and merged records in a performance log according to the succession of their associated time intervals.

- 15. (original) A method according to claim 1 additionally comprising merging selected records to form a merged record with a quality characterization of poor time and a duration equal to the sum of the duration of the intervals associated with the merged records.
- 16. (original) A method according to claim 1 additionally comprising selecting a set of records corresponding to a continuous succession of time intervals and merging the selected set to form a merged record provided the memory required to store the merged record is less than the memory required to store the selected set of records.
- 17. (original) Computer executable software code stored on a computer readable medium for making a computer execute the method of claim 1.
- 18. (original) A programmed computer, which stores computer executable program code for making the computer execute the method of claim 1.
- 19. (original) A computer readable medium having computer executable software code stored thereon, which code is for making a computer execute the method of claim 1.

20. (currently amended) A processor for carrying out performance monitoring in a communications network, wherein the processor comprises:

an input for receiving an incoming signal to which performance monitoring is to be applied;

an input for receiving a clock signal; and

processing means for carrying out the following instructions:

monitor a signal over time by allocating a current signal quality characterization to the signal, selected from at least three two such signal quality characterizations;

identify a plurality of time intervals making up a continuous succession of such time intervals, such that a current time interval is terminated and a next time interval is initiated each time the signal quality characterization allocated to the signal changes; and

generate a record of each identified time interval,

wherein the at least <u>three</u> two signal quality characterizations are selected from the following:

Perfect Time Interval (PT), which is allocated to the signal where no errors are detected on the signal;

Errored Time Interval, which is allocated to the signal where errors are detected on the signal in a unit time in insufficient numbers to make a service carried by the signal unavailable;

Severely Errored Time Interval, which is allocated to the signal where errors are detected on the signal in a unit time in sufficient numbers to make a service carried by the signal unavailable;

Unavailable Time Interval (UAT), which is allocated to the signal where a service carried by the signal is unavailable; and

Poor Time Interval (PrT), which is allocated to the signal where a sequence of at least two of the above characterizations are detected on the signal.

21. (original) A processor according to claim 20 which is located in a network element of the communications network.

- 22. (original) A processor according to claim 20 for monitoring a communications path and which is located in a network element of the communications network, which network element terminates the communications path.
- 23. (previously presented) A processor according to claim 20 wherein the processing means is additionally configured for generating a performance log in a memory using the records.

## 24. (cancelled)

- 25. (previously presented) A processor according to claim 20 wherein the processing means is configured for monitoring the signal over successive log periods and for generating a performance log using the records for each log period.
- 26. (previously presented) A processor according to claim 20 wherein the processing means is configured for generating a record for each interval which comprises at least the length of the interval and the signal quality characterization allocated for the interval.
- 27. (previously presented) A processor according to claim 20 wherein the processing means is configured for generating a performance log made up of records stored in accordance with the succession of time intervals.
- 28. (previously presented) A processor according to claim 20 wherein the processing means is configured for generating a performance log by manipulating selected records to reduce the amount of memory required to store the records while intelligently degrading their accuracy.
- 29. (previously presented) A processor according to claim 20 wherein the processing means is configured for selecting sets of records corresponding to continuous

successions of time intervals, and merging the selected sets to form a merged record.

30. (previously presented) A processor according to claim 20 wherein the processing means is additionally configured for carrying out the following:

designating some records as primary records and others as secondary records;

selecting sets of secondary records corresponding to continuous successions of time intervals; and

merging the selected sets to form a merged record.

31. (previously presented) A processor according to claim 20 wherein the processing means is additionally configured for carrying out the following:

designating records as primary records if they fall within one or more sets of the longest records having a selected quality characterization and designating other records as secondary records;

selecting sets of secondary records corresponding to continuous successions of time intervals; and

merging the selected sets to form a merged record.

32. (previously presented) A processor according to claim 20 wherein the processing means is additionally configured for carrying out the following:

designating some records as primary records and others as secondary records;

selecting sequences of secondary records corresponding to continuous successions of time intervals which are located between two primary records; and merging the selected sets to form a merged record.

33. (previously presented) A processor according to claim 20 wherein the processing means is additionally configured for carrying out the following:

designating some records as primary records and others as secondary records;

selecting sets of secondary records corresponding to continuous successions of time intervals; and

merging the selected sets to form a merged record;

wherein secondary records are designated as such according to one or more of the following:

records representing the shortest intervals of time; and records corresponding to the highest densities of continuous successions of time intervals.

- 34. (previously presented) A processor according to claim 20 wherein the processing means is additionally configured for monitoring the amount of memory required to store the records, and when the amount of memory reaches a predetermined limit, selecting sets of records corresponding to continuous successions of time intervals, and merging the selected sets to form a merged record so as to reduce the amount of memory required to store the records.
- 35. (previously presented) A processor according to claim 20 wherein the processing means is additionally configured for merging selected records to form a merged record with a quality characterization of poor time and a duration equal to the sum of the duration of the intervals associated with the merged records.
- 36. (currently amended) Control logic configured for carrying out performance monitoring in a communications network wherein the control logic comprises:

an input for receiving an incoming signal to which performance monitoring is to be applied;

an input for receiving a clock signal; and logic means for carrying out the following instructions;

monitor a signal over time by allocating a current signal quality characterization to the signal, selected from at least three two such signal quality characterizations:

identify a plurality of time intervals making up a continuous succession of such time intervals, such that a current time interval is terminated and a next time interval is initiated each time the signal quality characterization allocated to the signal changes; and

generate a record of each identified time interval,

wherein the at least  $\underline{\text{three}}$  two signal quality characterizations are selected from the following:

Perfect Time Interval (PT), which is allocated to the signal where no errors are detected on the signal;

Errored Time Interval, which is allocated to the signal where errors are detected on the signal in a unit time in insufficient numbers to make a service carried by the signal unavailable;

Severely Errored Time Interval, which is allocated to the signal where errors are detected on the signal in a unit time in sufficient numbers to make a service carried by the signal unavailable;

Unavailable Time Interval (UAT), which is allocated to the signal where a service carried by the signal is unavailable; and

Poor Time Interval (PrT), which is allocated to the signal where a sequence of at least two of the above characterizations are detected on the signal.

- 37. (original) Control logic according to claim 36 which is located in a network element of the communications network.
- 38. (original) Control logic according to claim 36 for monitoring a communications path and which is located in a network element of the communications network, which network element terminates the communications path.

39. (currently amended) A network element for carrying out performance monitoring in a communications network comprising;

processing means for monitoring a signal over time by allocating a current signal quality characterization to the signal, selected from at least three two such signal quality characterizations; and

processing means for identifying a plurality of time intervals making up a continuous succession of such time intervals, such that a current time interval is terminated and a next time interval is initiated each time the signal quality characterization allocated to the signal changes; and

processing means for generating a record of each identified time interval,

wherein the at least three two signal quality characterizations are selected from the following:

Perfect Time Interval (PT), which is allocated to the signal where no errors are detected on the signal;

Errored Time Interval, which is allocated to the signal where errors are detected on the signal in a unit time in insufficient numbers to make a service carried by the signal unavailable;

Severely Errored Time Interval, which is allocated to the signal where errors are detected on the signal in a unit time in sufficient numbers to make a service carried by the signal unavailable;

Unavailable Time Interval (UAT), which is allocated to the signal where a service carried by the signal is unavailable; and

Poor Time Interval (PrT), which is allocated to the signal where a sequence of at least two of the above characterizations are detected on the signal.

40. (original) A network element according to claim 39 for monitoring a communications path, which network element terminates the communications path.
